The preceding paper described our numerical index of carcinogenic potency, the TD<sub>50</sub>, and the statistical procedures adopted for estimating it from experimental data. This paper presents the Carcinogenic Potency Database, which includes results of about 3000 long-term, chronic experiments of 770 test compounds. Part II is a discussion of the sources of our data, the rationale for the inclusion of particular experiments and particular target sites, and the conventions adopted in summarizing the literature. Part III is a guide to the plot of results presented in Part IV. A number of appendices are provided to facilitate use of the database. The plot includes information about chronic cancer tests in mammals, such as dose and other aspects of experimental protocol, histopathology and tumor incidence, TD<sub>50</sub> and its statistical significance, dose response, author's opinion and literature reference. The plot readily permits comparisons of carcinogenic potency and many other aspects of cancer tests; it also provides quantitative information about negative tests. The range of carcinogenic potency is over 10 million-fold.

## Part I: Introduction

This paper presents the Carcinogenic Potency Database, which includes data on approximately 3000 long-term, chronic animal experiments with about 770 chemicals. The preceding paper (1) described our numerical index of carcinogenic potency, the TD<sub>50</sub>, and the statistical procedures adopted for estimating it from experimental data. In a simplified way, TD<sub>50</sub> may be defined as follows: for a given target site(s), if there are no tumors in control animals, then TD<sub>50</sub> is that chronic dose rate in mg/kg body weight/day which would induce tumors in half the test animals at the end of a standard lifespan for the species. Since the tumor(s) of interest often does occur in control animals, TD<sub>50</sub> is more precisely defined as: that dose rate (in mg/kg body

weight/day) which, if administered chronically for the standard lifespan of the species, will halve the probability of remaining tumorless throughout that period. A TD<sub>50</sub> can be computed for any particular type of neoplasm, for any particular tissue, or for any combination of these.

Part II of this paper discusses the sources of bioassay results and the rationale for including particular experiments and particular target sites in the database. The conventions adopted in summarizing and standardizing the literature are also described. In Part IV we present a plot of the database. In order for the reader to use this plot most effectively, Part III includes a full description of the contents, variable by variable. Several appendices which define codes and give additional details about particular tests are included after the plot.

Efforts to use animal bioassays in the evaluation of the potential health risks of chemicals to humans have been hampered by the lack of a standardized method to compare experimental results. Experimental protocols as well as the type of information reported in the literature are quite diverse. Moreover, quantitative estimates of carcinogenic potency have not yet been applied to the results of tests on a broad range of chemicals.

Our Carcinogenic Potency Database is an attempt to quantify and standardize the animal bioassay literature

and to organize it systematically. It has become clear that the dose levels of different chemicals which induce tumors in rats and mice vary enormously, i.e., some chemicals are observed to be more powerful carcinogens than others. Moreover, the total number of known and suspected carcinogens, both natural and man-made, to which humans are exposed is much larger than previously thought (2). Therefore, quantifying the carcinogenic potency of various chemicals is one important aspect of developing a policy response to the problem of chemical hazards to humans.

Ideally, for human risk assessment and regulatory policy, one would like to have quantitative information about the potency of various chemicals in man, but with rare exceptions this information is not available. The next best source of information is the extensive literature on animal bioassays. Although it is clear that animal models are not a completely satisfactory model for man, it is essential to examine the published animal literature in a more organized and quantitative way.

We would like to emphasize the complexities of animal bioassay results, and to caution that no single number such as the TD<sub>50</sub> fully describes the data. We have included in the database presented in Part IV, information about a variety of factors which are important in the interpretation of bioassays, such as: the TD<sub>50</sub> and its statistical significance, the species and strains which have been tested chronically, the route and duration of compound administration, the tumor types, the proportion of animals with specific types of tumors in dosed and control groups, the shape of the dose-response curve and the author's opinion about carcinogenicity.

Future analyses of this database should help to identify similarities and differences in response among strains and species. In addition, quantitative estimates of carcinogenic potency should be useful in determining the extent to which potency in animals is predictable from mutagenic potency calculated from short-term tests.

A word of caution is necessary about the limitations of the database. We have not attempted to evaluate whether or not a compound is a carcinogen; rather, we report the opinions of the authors whose data we present, as well as the statistical significance of the TD<sub>50</sub> calculated from their results. Moreover, the database contains only long-term tests which fit a set of criteria designed to measure potency, and therefore does not cover all cancer tests or all carcinogens. The limitations and criteria are discussed further in Part II.

## Part II: Materials and Methods of the Carcinogenic Potency Database

### Sources of Data

One major goal of the Carcinogenic Potency Database has been to obtain data which would give the best estimates of carcinogenic potency, i.e., experiments for

which detailed time-to-tumor data would permit adjustment for the gross effects of intercurrent mortality (see preceding paper). Full lifetable information was available for the calculations of potency from the Carcinogenesis Bioassay Program of the National Cancer Institute (NCI)/National Toxicology Program (NTP) and from a set of bioassays of aromatic amines (3-5). For all other estimates of potency from the published literature, we have calculated TD<sub>50</sub> using the final proportions of animals with tumors, since only this summary information is consistently published. A description of each of these two sources of data, (1) NCI/NTP Bioassays and (2) bioassays in the published literature, is given below.

**NCI/NTP Bioassays.** The Carcinogenesis Bioassay Program of the NCI/NTP was designed to use a similar experimental protocol for a large number of compounds, and to report results in a consistent format including full histopathology. We obtained computer tapes containing the individual animal pathology tables from the Chemical Package Report of the Carcinogenesis Bioassay Data System (6) for which Technical Reports were published prior to July 1980. These tapes contain information about the time of death (in weeks) and full histopathology for each animal in each experiment. By using the tapes in combination with the series of technical reports (Appendix 15) published by NCI/NTP we have been able to estimate a TD<sub>50</sub> for each site which was evaluated as treatment-related, as well as for each site found to be statistically significant but not considered evidence for carcinogenicity, in the text of the technical report.

The Carcinogenesis Bioassay Program protocol recommends that tests be conducted in two species of rodents (rats and mice) with both sexes tested individually at the maximally tolerated dose and half that dose, and includes a control group (vehicle control where appropriate) (7). The actual conduct of the bioassays published prior to July 1980 varied from one experiment to another, and details about each are given in the plot in Part IV. (An experiment is defined here as the dose groups and control group for one sex in one species from a single research report.) Comparisons of results from the 776 NCI/NTP experiments are particularly useful for the following reasons: our analyses utilized full lifetable data; each compound was usually tested in both sexes of rats and mice; the same mouse hybrid, B6C3F1, was used throughout; the rat bioassays utilized mostly the Fischer F344 strain, and less frequently either the Osborne-Mendel or Sprague-Dawley stocks; test agents were usually administered by an oral route, and dosing continued for the majority of the animals' lives (18-24 months); and terminal sacrifice was usually performed after 21 to 25 months on test. For many of the reports, the quality of the pathology was monitored by a detailed review system (8). For the others, target sites were always selectively reviewed to verify the conclusions in the Report.

**Bioassays in the Published Literature.** In the literature at large, experimental designs as well as the

authors' choice of information to report, are quite diverse. For the Carcinogenic Potency Database, we have developed a set of standard criteria, and experiments from the literature have been included only if they meet all of the following conditions: (A) animals on test were mammals; (B) administration was begun early in life (100 days of age or less for rats, mice and hamsters); (C) route of administration was diet, water, gavage, inhalation, intravenous or intraperitoneal injection (i.e., where the whole body was more likely to have been exposed rather than only a specific site, as with subcutaneous injection or skin painting); (D) test agent was administered alone, rather than in combination with other chemicals; (E) exposure was chronic, with not more than 7 days between administrations; (F) duration of exposure was at least one-fourth the standard lifespan for that species; (G) duration of experiment was at least half the standard lifespan for that species; (H) research design included a control group; (I) research design included at least 5 animals per group; (J) surgical intervention was not performed; (K) pathology data were reported for the number of animals with tumors rather than the total number of tumors; (L) results reported were original data, rather than secondary analyses of experiments already reported by other authors.

A search of the published literature through July 1981 was conducted for all bioassays which met the standard criteria, whether or not the authors considered the test agent related to tumor induction. The literature search covered the Public Health Service publication, *Survey of Compounds Which Have Been Tested for Carcinogenic Activity 1948–1973* and 1978 (9). Since the years 1974–1977 and 1979–1981 are not covered by the PHS Survey, a search of the cancer journals which contain most of the bioassay literature was conducted for those years, including *Carcinogenesis Abstracts* and the following journals through July 1981: *British Journal of Cancer*, *Cancer Letters*, *Cancer Research*, *Carcinogenesis*, *Chemosphere*, *Environmental Health Perspectives*, *European Journal of Cancer*, *Food and Cosmetics Toxicology*, *Gann*, *International Journal of Cancer*, *Journal of Cancer Research and Clinical Oncology* (formerly *Zeitschrift fur Krebsforschung und Klinische Onkologie*), *Journal of Environmental Pathology and Toxicology*, *Journal of Toxicology and Environmental Health*, *Journal of the National Cancer Institute*, and *Toxicology and Applied Pharmacology*. The monographs on chemical carcinogens prepared by the International Agency for Research on Cancer (1972–1981) and *Current Contents* (1976–1981) were also used.

From the literature search, more than 2000 experiments on approximately 600 chemicals met the inclusion criteria and are in the database. Most experiments used rats or mice, many used hamsters, and a small number used dogs, monkeys, tree shrews or bush babies. For any single chemical, the number of experiments in the database may vary. For example, some chemicals may

have only one test in one sex of one species, while others may have multiple tests including both sexes of a few strains of rats and mice, utilizing different protocols. Similarly, the number of TD<sub>50</sub> values reported for an experiment may vary, depending upon the results of the test and what the author reported.

Because we have adhered quite strictly to the standard inclusion criteria and the publication date of July 1981, a number of well-known carcinogens are not in the database. There are no single injection or skin painting tests, and no experiments on initiation-promotion. Bioassays of particulate or fibrous matters are not included, e.g., asbestos, cigarette smoke and dusts. For a few carcinogens, the only tests which met the inclusion rules were negative, and therefore no positive results are given in the plot\*.

Although we have excluded mixtures of chemicals from the database, some commercial preparations such as pesticides and drugs to which humans are frequently exposed have been included. A few exceptions have been made about the cutoff date of July 1981, either because partial results were published before that date or because the data were relevant for our own analyses already in progress.

For the relatively small literature on the long-lived nonhuman primates, we have relaxed some of our standard rules in order to include the maximum number of experiments (see Appendix 13).

### Selection of Tissue and Tumor Types for Calculation of Carcinogenic Potency

In order to standardize the very diverse bioassay literature, a great many decisions have had to be made in the construction of the database. Such decisions were based on two major considerations: to provide the most accurate estimates of TD<sub>50</sub> and to provide a large resource with comparable data to facilitate the analysis of the results of animal cancer tests.

Our choice of which sites and pathology to report from the published literature is limited by what individual authors have reported, and this varied considerably from paper to paper. The precision of pathology analyses has increased over the years, and nomenclature has changed, thus creating further differences in the literature.

For reasons of both accuracy and consistency throughout the database, our general approach has been to calculate a TD<sub>50</sub> for each category of neoplasm, benign or malignant, which an author evaluated as treatment-related, regardless of the statistical or biological basis for the evaluation. (Hyperplasia and non-neoplastic

\*For seven chemicals evaluated as having sufficient evidence for carcinogenicity by IARC, only negative tests met the inclusion rules: cadmium chloride, cadmium sulfate, epichlorohydrin, glyceraldehyde, isosafrole, mestranol, 2-nitropropane (10). These are flagged in the plot of the database with a double asterisk (\*\*) after the chemical name.

lesions are not included in the database.) In addition, a TD<sub>50</sub> has been estimated for the category "all tumor-bearing animals" (TBA) wherever this was reported.

In order to provide information which would permit comparisons of target sites across experiments, an additional category of histopathology was developed for the database—"mandatory sites." Whenever there is adequate documentation in the published paper or report, a TD<sub>50</sub> is estimated for tumors of the liver in rats and mice, and for tumors of the lung in mice. These tissues were selected as mandatory because they occurred most often in a frequency count of the positive sites in the NCI/NTP bioassays. From the general literature, whenever possible, we have also taken both the liver and lung as mandatory sites in hamsters, dogs and monkeys.

In summary, for each experiment in the database, a TD<sub>50</sub> is calculated whenever documentation is adequate for the following categories: (1) each target site evaluated by the author as treatment-related; (2) mandatory sites; (3) all tumor-bearing animals (TBA).

Some special considerations about selection of pathology for the calculation of TD<sub>50</sub> from each source of data are as follows.

**NCI/NTP Bioassays.** From the NCI/NTP Technical Reports, TD<sub>50</sub> values have been calculated for all categories of tissues and tumors listed in the Tables of Analyses of Primary Tumors as positively related to dose. (See description of statistical tests in Technical Reports.) For our plot we always report a target site when there was a positive evaluation in the text of the report; however, in the absence of a positive evaluation, sites that are reported in the statistical tables but that are not considered treatment-related, are included only if the TD<sub>50</sub> itself is significant at the  $p < 0.05$  level (two-tailed  $p$ -value for the test that the slope of the dose response is different from zero). We refer to these cases as "statistical sites" to indicate that the report did not evaluate them as evidence for carcinogenicity.<sup>†</sup>

Because the computer tapes from the Individual Animal Pathology Tables of the NCI/NTP contain individual pathology results, it has been possible to calculate a TD<sub>50</sub> for a composite category of all tumors which the report evaluated as associated with administration of the test compound. For purposes of risk assessment this seems prudent, despite the bias which this can, in principle, cause. It has not been possible to formulate such a composite category for other experiments in the database.

<sup>†</sup>In a few cases, a compound was evaluated in the Technical Report as negative in rats and mice of both sexes, yet the statistical significance associated with a TD<sub>50</sub> "statistical site" is  $p < 0.01$ . For these cases which raise questions about the evaluation of the compound, we have forwarded our findings to the NTP. For the NCI bioassay of Kepone, the Technical Report's positive evaluation of hepatocellular carcinomas in male and female rats was based on pooled controls. No TD<sub>50</sub> values were calculated for these sites however, because the lifetable data for the pooled controls were not available. Therefore, on the plot the negative opinion for male and female rats reflects only the evaluation for matched controls.

In the NCI/NTP data, for each mandatory site, a TD<sub>50</sub> is estimated for a specific combination of tumors. These were selected because they are the common histopathology reported for the specified tissue by the NCI/NTP. For the liver, neoplastic nodule, hepatocellular adenoma, and hepatocellular carcinoma are combined in the mandatory TD<sub>50</sub>. For the lung, alveolar/bronchiolar adenoma and alveolar/bronchiolar carcinoma are combined. In all cases, the incidence represents the proportion of animals with any of the tumors; animals with multiple tumors of the given tissue are counted only once. For the category TBA, we have excluded interstitial-cell tumors of the testis for Fischer 344 rats, since these tumors occur spontaneously in nearly all male animals by the end of their standard lifespan.

**Bioassays in the Published Literature.** Authors of papers published in the general literature rarely indicate which animals were diagnosed as having more than one tumor. Therefore, it has been generally impossible for us to combine data on various tumors within a single tissue, or to specify particular tumor types which should be included in mandatory sites. To attempt to combine incidence data would risk multiple counting of animals.

For the mandatory sites from the published literature, a TD<sub>50</sub> is estimated for individual tumor types reported in the mandatory tissue, as well as for any combination of tumors which is reported or could be created for that tissue without risking multiple counting.

In the interest of completeness, we have added to the database results for tissues and tumors in the literature which the authors did not consider treatment-related, but which we calculate as statistically significant (standard chi-square test, one-sided  $p < 0.05$ ).

Throughout the database, when we report results separately for benign and malignant tumors at a given site in a single experiment, we often do not know whether the author counted animals only for the most malignant tumor. For example, we may not know whether the proportion of animals with adenomas represents only those animals which did not have carcinomas.

## Estimation of Average Daily Dose Level

Because a variety of routes of administration, dosing schedules, species, strains, and sexes are used in carcinogenesis bioassays, some standardization of dose is required for a single index of potency. Our convention in estimating TD<sub>50</sub> is to determine for each dose group in an experiment the daily dose rate (in mg/kg of body weight) averaged over the duration of the experiment. It may be that a different measure of dose (such as mg/cm<sup>2</sup> surface area) will prove to be most similar across species (11).

To convert parts per million (ppm) or percent in the food, water or air, into milligrams per kilo body weight during the dosing period, we assume 100% absorption and then use a set of standard values for each sex of

each species, including body weight and average intake per day (Table 1). Using standard values, the daily dose rate is calculated as follows:

$$\text{Dose rate} = \frac{\text{dose} \times \text{intake/day} \times \text{number of doses/week}}{\text{animal weight} \times 7 \text{ days/week}}$$

or, equivalently,

$$\begin{aligned} \text{Dose rate} &= \\ &\text{dose} \times \text{intake/day as a proportion of body weight} \\ &\quad \times \text{proportion of week dose is administered} \end{aligned}$$

In an experiment where the animals were dosed the entire time on test this value would equal the average daily dose level. For example, in a bioassay of male mice fed 50 ppm of some test agent in the diet for the entire time on test, the calculation would be:

$$\begin{aligned} \text{Dose rate} &= 50 \text{ ppm} \times 0.12 \times 1 \\ &= 6 \text{ mg/kg body weight/day} \end{aligned}$$

In this example, the exposure time is equal to the experiment time.

In using standard values we recognize that there is no single factor which precisely reflects the entire experimental literature. For example, strains within a species will vary in weight; younger animals have lower body weight and food intake than adults; some test agents will reduce appetite due to taste; or illness may result in loss of appetite. However, the values used here are

within reasonable limits of those usually found in the published literature and are unlikely to produce substantial error.

In many experiments the administration of the test compound is stopped before the terminal sacrifice or before the death of the last animal. In such cases, averaging the dose over the course of the experiment will lower the daily dose level. By convention we take the total dose administered and spread this over the entire experimental period; thus, for male mice which are dosed at 50 ppm in the feed for 70 weeks and then continued on test to 100 weeks, the dose is considered as equivalent to 35 ppm for the entire 100 weeks, (i.e.,  $50 \text{ ppm} \times 70/100$ ), resulting in a 4.2 mg/kg body weight/day average dose. In calculating the dose, we utilize the concept of exposure time (the period of active treatment) and experiment time (the actual time on test). When terminal sacrifice is performed, the experiment time is the length of time from the start of the experiment to sacrifice. When, however, animals are permitted to survive to natural death, we define experiment time by using the time of the death of the last dosed animal.

### Extrapolation of TD<sub>50</sub> to the Standard Lifespan

TD<sub>50</sub> is defined in terms of the dose rate that will halve the probability of remaining tumor-free at the end of a standard lifespan. For each species the assumed value for the standard lifespan is given in Table 1; these values are within reasonable limits usually found in the

**Table 1. Standard values for dose calculation: animal lifespans, weights, and intake by diet, water, and inhalation.<sup>a</sup>**

Experimental animal	Sex	Standard lifespan, yr <sup>b</sup>	Weight kg <sup>c</sup>	Food/day, g <sup>c</sup>	Food as % body weight/day	Water, mL/day <sup>d</sup>	Inhalation volume, L/min <sup>e</sup>
<b>Rodents</b>							
Mouse	Male	2	0.03	3.6	12.00	5	0.03
	Female	2	0.025	3.25	13.00	5	0.03
Rat	Male	2	0.5	20	4.00	25	0.10
	Female	2	0.35	17.5	5.00	20	0.10
Hamster	Male	2	0.125	11.5	9.20	15	0.06
	Female	2	0.110	11.5	10.45	15	0.06
<b>Monkeys</b>							
African green ( <i>Cercopithecus aethiops</i> )	Both	20					
Cynomolgus ( <i>Macaca fascicularis</i> )	Both	20					
Rhesus ( <i>Macaca mulatta</i> )	Both	20					
<b>Prosimians</b>							
Bush babies ( <i>Galago crassicaudatus</i> )	Both	10					
Tree shrews ( <i>Tupaia glis</i> )	Both	4.5					
Dog	Both	11	16	400	2.50	500	

<sup>a</sup>Although values sometimes vary depending on the source, those given here are within reasonable limits of those usually found in the published literature. No value is given when this information was not necessary for our dose calculation.

<sup>b</sup>Rat and mouse: data based on NCI trichloroethylene bioassay (12); hamster: data of Williams (13); nonhuman primates: data of S. M. Sieber (Laboratory of Chemical Pharmacology, NCI, National Institute of Health, Bethesda, MD.), personal communication; bush babies: ages adapted from Dittmer (14); tree shrews: data of D. J. Reddy (Northwestern University, Chicago, IL.) personal communication; dog: data of M. S. Redfearn (Division of Animal Resources, University of California, Berkeley, CA.) personal communication.

<sup>c</sup>Rat and mouse: data based on NCI trichloroethylene bioassay (12); hamster and dog: data of D. Brooks (University of California, Davis) personal communication.

<sup>d</sup>Mouse, rat and dog: data from NIOSH (15); hamster: data from Hoeltge, Inc. (16).

<sup>e</sup>Mouse: data of Sanoskij (17); rat: data of Baker et al. (18); hamsters: data of Guyton (19).

published literature. The use of two years as standard for rats and mice reflects both the standard NCI/NTP protocol and values that appear frequently in the literature.

When an experiment is terminated before the standard lifespan, animals are not at risk of developing tumors later in life. Thus the number of tumors found will be reduced, and the  $TD_{50}$  will be greater than the true  $TD_{50}$ , i.e., the compound will appear to be less potent than it actually is. Because tumor incidence increases markedly with age, our convention has been to adopt as a correction factor  $f^2$ , where  $f = \text{experiment time}/\text{standard lifespan}$ . The basis for selecting  $f^2$  is discussed in the preceding paper (1).

Note that the correction factor  $f^2$  is based on the time the animals are on test, rather than upon age. In an experiment which began when the animals were 6 weeks of age and which terminated when the animals were 100 weeks of age, the experiment time is 94 weeks. Thus,  $TD_{50}$  is defined in terms of the dose rate which would be administered throughout life, from birth to death, or the entire standard lifespan.

By omitting from the database any experiments lasting less than half the standard lifespan for that species, the necessity for great extrapolation has been reduced. Few bioassays in any species are continued for much longer than the period we have adopted for a standard lifespan, so the reverse correction is minimal.

Taking the example above of male mice fed some test agent at 50 ppm for 70 weeks and then continued on test for 30 more weeks, the experiment time would be 100 weeks. The standard lifespan for mice is 104 weeks, so the extrapolation factor would be  $(100/104)^2$ , or 0.92. Further details about the estimation of  $TD_{50}$  can be found in the preceding paper (1).

We have made an exception to the experiment-length rule by including in the database bioassays of four compounds in nonhuman primates for which the results were positive in a short time and the standard lifespan is quite long. For these experiments, considerable extrapolation has been required, thus making the estimate of  $TD_{50}$  less reliable (see Appendix 13).

### Range of Carcinogenic Potency

The  $TD_{50}$  values we have estimated according to the rules and conventions just described are presented in Part IV. The plot format provides a systematic means of distinguishing among the carcinogenic potencies of a variety of chemicals. The range of  $TD_{50}$  values is more than 10 million-fold.

For male rats, the range of carcinogenic potency is shown in Figure 1, where we present the most potent  $TD_{50}$  values for a selected group of compounds which were evaluated as tumorigens in either an NCI/NTP Technical Report or the general literature. In each case, we have indicated the value for the most potent  $TD_{50}$  for a target site(s) which was considered positive, and for which the statistical significance of  $TD_{50}$  is less than

0.01. At the two extremes are the most potent  $TD_{50}$  values for 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD),  $TD_{50} = 101 \text{ ng}$ , and for FD&C Green No. 1,  $TD_{50} = 5.98 \text{ g}$ .

It is our intention to present analyses of potency in future publications which will discuss such issues as comparisons of potency across species and strains, and among different bioassays of the same chemical.

### Part III: Guide to the Plot of the Carcinogenic Potency Database

The results of our estimates of  $TD_{50}$  and the standardization of the bioassay literature are summarized and presented graphically below in the plot of the database. This plot includes information on many aspects of the 2944 experiments it summarizes. The following description of the plot, in conjunction with the appendices, is intended as a guide for the reader to facilitate use of the data. Because so much information is included in the

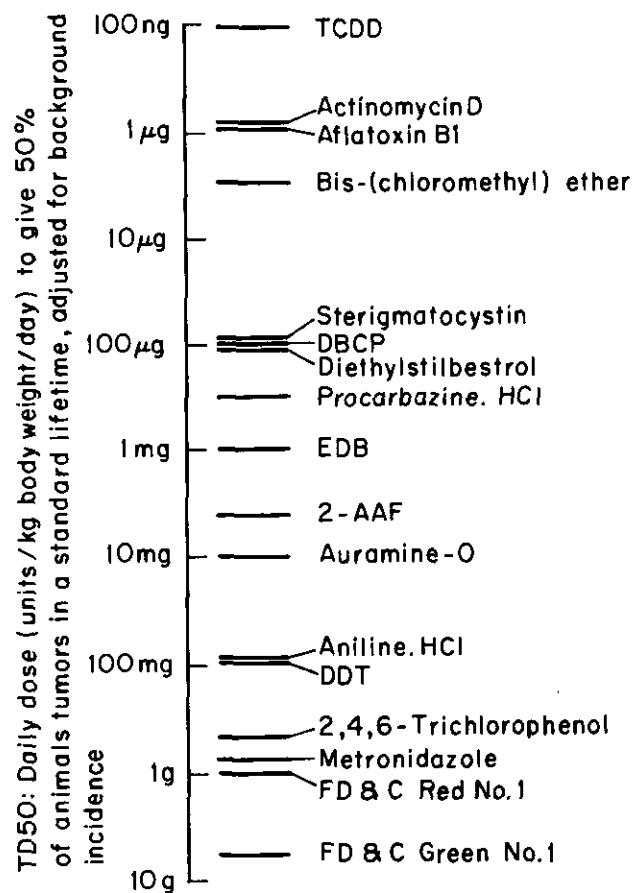

FIGURE 1. Range of carcinogenic potency in male rats.

output, the reader may find it helpful to go over the description once and to refer back to specific variables when using the plot.

The plot covers two facing pages and is organized alphabetically by chemical name. The left side includes a logarithmic scale of TD<sub>50</sub> values on which is plotted the TD<sub>50</sub> for the most potent site in each experiment. Experiments are listed under the name of the test agent, and each experiment can be identified by a unique number in the plot.

Figures 2 and 3 show an example from the plot of one experiment on 1,2-dibromoethane from the NCI/NTP bioassays, which will be used to describe the variables included in the plot, the codes and conventions, and the appendices. At the top of the example, as at the top of the plot of the entire database, is a two-line header describing the type of information in each field. The header should be read across using both lines together, first top line "Spe," then bottom line "Sex," then top line "Strain", etc. Each title in the header begins where the data it describes begins, with the exception of "AuOp" and "Brkly Code" which are in the last column on each side. Immediately beneath the header in this example, we have inserted a set of numbers (1)–(28) which will be used in the text to give details of the information in each field; this set of numbers does not appear in the actual output.

(1) The chemical name in capitals is indicated under (1) in the top line for a set of experiments. An alphabetical list of all chemicals in the plot is given in Appendix 1. Common synonyms are also provided which refer the reader to the compound name used in the plot e.g., ethylene dibromide (see 1,2-dibromoethane). A list of the chemicals sorted by Chemical Abstracts Service (CAS) registry number is presented in Appendix 2. Also under the number (1), immediately

below the chemical name, is the unique plot number for each experiment, i.e., one sex of one species from one research report. Since only one experiment is used in this example, it is assigned the number one. In the larger output, each new number indicates a separate experiment. A set of lower case letters—in the example "a" through "f"—identifies each TD<sub>50</sub> calculated for that same experiment using a different set of sites and/or histopathology; only the most potent site is plotted on the graph.

(2) The species used in this experiment is indicated in the column headed by "Spe." The letter "M" refers to mice, "R" to rats, "H" to hamsters and "D" to dogs. Other test animals are indicated by an "N" for prosimians and a "P" for monkeys.

(3) The sex is indicated by "f" for female, "m" for male. Occasionally an author will report data only for both sexes together, and in these cases the notocode "b" for both is used.

(4) The strain or stock of animal is reported as a three-letter code under "Strain"; a list of all strain codes and definitions appears in Appendix 3. Strains are coded just as they are referred to in the original publication. No attempt has been made to standardize the strain names; therefore, if different nomenclature is used by two authors who actually tested the same strain, then two different codes are used in the database. For monkeys and prosimians, this column is used for the species code, e.g., "rhe" for rhesus.

(5) The route of administration is indicated in the header line by "Route" and reported as a three-letter code. In the example, "gav" stands for gavage. Other routes are listed in Appendix 4 and use mnemonic codes like "eat" for administration in the diet.

(6,7) The site and histopathology used in the calculation of the TD<sub>50</sub> are reported in these columns, and are

FIGURE 3. Right side of database plot.

marked in the header line by "Site" and "Hist." Each is indicated by a three-letter code, and the respective codes and definitions are provided in Appendices 5 and 6. Three-letter codes have been created so that they are similar to the words they represent; for example line 1a reports "sto sqc" which stands for stomach, squamous-cell carcinoma; and line 1c reports "lun a/a" for lung, alveolar/bronchiolar adenoma.

For the NCI/NTP bioassays, the pathology nomenclature is identical to that reported in the Technical Reports and/or on the computer tapes. For the general literature, the nomenclature reflects exactly the terminology employed by the original authors in their published papers. The operational rule has been to retain what is in the published paper and not to reinterpret or rename any diagnostic categories. Thus, when authors use different nomenclature for the same tissue or morphologic type of tumor, two different codes are used in the database. Occasionally it has been necessary to replace an adjective used for a tissue with a noun, e.g., the database uses kidney when renal is used in a paper. Some special considerations about the reporting of site and histopathology information from each source of data are as follows.

**NCI/NTP Bioassays.** In the 1,2-dibromoethane example (Figs. 2 and 3), certain tissue and tumor codes are given in capital letters; these denote particular mixes of sites or tumor types from the NCI/NTP bioassays; capital letters are not used for other sources of data. When these capitals appear, additional information about the specific pathology is presented on the right side of the plot, where the header line reads "Citation or Pathology" in field (27). These special capitalized codes are used in the plot when the calculation of TD<sub>50</sub> is based on special mixes of tissue and tumor types from the NCI/NTP bioassays.

1. The mandatory sites are denoted by "MXB" (for "Mix Berkeley") to indicate that the site was created especially for the database and is not based upon the NCI/NTP evaluations in the Technical Reports. For every NCI/NTP experiment, the same sites are given per species: liv MXB (liver mandatory), lun MXB (lung mandatory) and TBA MXB (all tumor-bearing animals) for mice; liv MXB and TBA MXB for rats. For the NCI/NTP bioassays, these mandatory sites are always listed as the last TD<sub>50</sub> values for the experiment, in the order TBA, liv, and lun. Thus in the example given here, lines 1d, e, and f, report for mice the TBA MXB, liv MXB, and then lun MXB. The specific pathology is given for liv MXB and lun MXB under column (27).

2. "MXA" (for "Mix Author") is used to denote a combination of sites or pathologies which is taken directly from the Technical Report Tables of Analyses of Primary Tumors, and denotes a mix of tissues or tumors created in those tables. In the example, the site and histopathology for line 16, "lun MXA" are listed in column (27). Whenever MXA appears, as in line 1b "lun MXA," the sites and/or histopathology which were combined are listed in column (27).

3. "MXB MXB" denotes that a combination of tissues and tumors has been created for the database, which consists of the aggregate of all sites and histopathology considered to be treatment-related in the NCI/NTP Technical Reports. In the example, in field (27) of line 1, MXB MXB is described as a combination of "lun: a/a, a/c; sto: sqc." (This stands for lung alveolar/bronchiolar adenoma, lung alveolar/bronchiolar carcinoma, and stomach squamous-cell carcinoma.)

**Bioassays in the Published Literature.** The site and pathology information from the literature experiments is given in the plot for individual tissues and tumors just as it is for the NCI/NTP bioassays. As described earlier, it is usually not possible to combine sites from the published literature because, unlike the data available from the NCI/NTP bioassays, information is seldom reported about multiple tumor incidence in the same animal. When an author does give information about aggregated tissue or tumor types, the code "mix" is used in the plot to denote that the specific sites or tumors are described in the paper. When the tumor types are not specified, the code "tum" is used. Mandatory sites from experiments in the literature are included in the database for the same tissues as the NCI/NTP bioassays. A TD<sub>50</sub> is calculated for any mix of tumors reported in the mandatory site and for individual tumor types as well;\* see, for example, "hydrazine sulfate" for female mice, lines 1434 and 1434a and b in the large plot. All codes are in lower case letters. Whenever an author reported results for all animals with malignant tumors separately from all animals with benign tumors, we have included a TD<sub>50</sub> for each category of "tba".

(8,9) The exposure and experiment times are indicated in the header line by "Xpo + Xpt." Exposure time is the period over which the test agent is administered; if administration was once a week for 40 weeks, for example, the exposure time is 40 weeks. Experiment time is the total time on test; it is not the age of the animals. It is measured from the start of the experiment to the time of death of the last dosed animal. Within a single experiment, all TD<sub>50</sub> values have the same exposure time and the same experiment time. Both times are always reported in the same units. When both are less than 100 weeks, exposure and experiment times are reported as "w" for weeks; when greater than this, "m" for months is used. For tests in long-lived experimental animals like dogs and nonhuman primates, "y" for years may also be used. When exposure time and experiment time are equal, then the duration of dosing was for the entire experiment. In Figure 2 lines 1a-1f, the mice were dosed for 53 weeks, and the experiment lasted a total of 78 weeks.

(10) Notes, indicated in the header line in (10), pro-

\*If an author reported many individual types of tumors in a mandatory tissue, and all are statistically nonsignificant, we have calculated TD<sub>50</sub> values for the tumor types with the highest incidence among dosed animals.

vide additional information about the experiment in single-letter codes which are defined in Appendix 7. This supplementary information is helpful in evaluating the experimental data. In the example, for instance, the notecode "s" is used to denote that survival was poor due to toxicity or disease and the notecode "v" that dosing was variable or irregular, e.g., dose level changed during the course of the experiment.

(11) The logarithmic scale is used for presenting the values of TD<sub>50</sub> and its confidence limits (in units/kilogram body weight/day). The plot extends from 100 nanograms to 10 grams. On the scale itself, the location of 100 ng, 1 µg, 10 µg, etc., is indicated by underscoring; the points for 5, 50, 500 are denoted by a colon (":"). For each experiment, only the TD<sub>50</sub> for the "most potent site" is plotted; this TD<sub>50</sub> is listed first. For other sites within an experiment, the TD<sub>50</sub> is not plotted, but all other information about it is given in the plot.

The "most potent site" is determined by ordering the TD<sub>50</sub> values in each experiment by statistical significance. If any TD<sub>50</sub> values are significant at the  $p < 0.01$  level, then these are listed first, in order of potency; then follow all TD<sub>50</sub> values with  $p < 0.10$  sorted in order of potency. Last, all other TD<sub>50</sub> values are listed in order of potency. We have excluded the category TBA from this sorting of the target sites and have listed it last. For the NCI/NTP bioassays, the mandatory sites are also excluded from this sorted order, and are listed at the end in the order TBA MXB, liv MXB, and lun MXB.

In the example of 1,2-dibromoethane (Fig. 2), there are two TD<sub>50</sub> values (excluding TBA) with statistical significance of  $p < 0.01$ . The TD<sub>50</sub> for MXB MXB is the more potent and thus appears first. The plotted point for this most potent site lies between 1 mg and 10 mg on the scale, and the estimated TD<sub>50</sub>, 3.74 mg, appears in the column to the right of the scale under the header title "TD50." These results indicate that 3.74 mg/kg body weight/day would halve the proportion of tumorless survivors at the end of a standard lifespan for mice (in the absence of all other causes of death).

(12) The TD<sub>50</sub> value on the plot is indicated by one of three symbols: "+" "±" or ">", depending upon the  $p$ -value associated with the TD<sub>50</sub> for the most potent site. In an experiment where the statistical significance of the TD<sub>50</sub> is  $p < 0.01$ , the symbol "+" is used, and the plotted point is the most potent estimate of TD<sub>50</sub>, i.e., the smallest value of TD<sub>50</sub> from among those with  $p < 0.01$ . In an experiment where the statistical significance is between 0.01 and 0.10 a "±" symbol is used to plot the most potent site. If there is no evidence for any statistical association, i.e., for all TD<sub>50</sub> values,  $p > 0.10$ , then the symbol ">" appears just to the right of the lower confidence limit. For these statistically nonsignificant experiments, the symbol ">" provides a lower bound for TD<sub>50</sub>, i.e., it is extremely unlikely that TD<sub>50</sub> could be less than (more potent than) the value plotted.

A special symbol "<+" is used for cases where 100% of all dosed animals had the tumor(s) of interest and the TD<sub>50</sub> was calculated with summary data; the "<+"

appears at the upper confidence limit. With summary data, only an upper bound, but no TD<sub>50</sub>, can be estimated in such cases.

Occasionally, the symbol for the most potent TD<sub>50</sub> is plotted with parentheses around it to indicate that the test did not meet our standard criteria; usually the experiment time was too short. All NCI/NTP bioassays have been included in the database, and some do not meet the criteria. For experiments in nonhuman primates, the criteria have been relaxed. (See Appendix 13.) For an example of such a case, see C.I. Direct Brown 95 for female rats, line 404 in the large plot.

The plot symbol is a convenient way to determine quickly the number of experiments reported for any particular test agent, since each experiment will have one symbol for its most potent TD<sub>50</sub>.

Since there are both statistical and nonstatistical uncertainties in the estimation of TD<sub>50</sub>, we have calculated 99% confidence intervals for it. A discussion is given in the preceding paper (1). Whenever the TD<sub>50</sub> calculation is based on lifetable data, as in the NCI/NTP bioassays and a set of experiments on aromatic amines, the symbol ":" denotes the confidence limits. When the TD<sub>50</sub> calculation is based on summary data, then the symbol ":" denotes the confidence limits.

In an experiment where the statistical significance of TD<sub>50</sub> is  $p < 0.01$ , both the lower and upper confidence limits are plotted. The calculated values for these intervals are presented on the right side of the plot in columns (20) and (21) (Fig. 3), where the header line reads "LoConf" and "UpConf" for lower confidence and upper confidence limits. In the example, the plotted confidence interval is 2.58–6.93 mg (Fig. 3), suggesting that the lower value would not reduce the proportion of tumorless survivors by half, while 5.55 mg/kg body weight/day would more than halve it.

In an experiment where the statistical significance of TD<sub>50</sub> is  $p > 0.01$ , the confidence interval will be open at the upper end. In such a case, the lower limit dose rate would be unlikely to halve the proportion of tumor-free survivors, but no statement can be made about the carcinogenic effect of higher doses. In such cases, there is no ":" or ":" to the right of the TD<sub>50</sub> on the plot.

When the plotted symbol is "<+" because 100% of the animals had tumors and we estimated TD<sub>50</sub> with summary data, the "<+" appears at the upper confidence limit. In such cases, the upper limit dose rate would induce tumors in all animals and the rate which would reduce the proportion of tumorless survivors by half cannot be estimated with only summary information.

Occasionally, for a TD<sub>50</sub> with statistical significance  $p < 0.01$ , the upper confidence limit is too large to be printed within the range up to 10 grams; in such rare instances the symbol for the upper confidence level also will not appear, although the value will be printed in the field headed UpConf (21).

(13) The value of each TD<sub>50</sub> is presented just to the right of the plot range (13) and includes the appropriate

units (per kg) of body weight per day. The symbol "no TD<sub>50</sub>" appears instead of a numerical value whenever 100% of the dosed animals had the tumor(s) of interest and the TD<sub>50</sub> was calculated with summary data. The symbol "no dre," for no dose-related effect, indicates that TD<sub>50</sub> is not estimable for some other reason. For statistically non-significant TD<sub>50</sub> values the numerical value may be impossibly large.

(14) The shape of the dose-response curve for each TD<sub>50</sub> appears in column (14) under the header "DR." The codes and definitions for the curvatures are listed in Appendix 8. The shape of the dose-response has been determined by a test for departure from linearity. If there was no significant departure from a linear dose response, then the curve shape is listed as linear, and the asterisk symbol "\*" appears. For experiments with three groups of animals including controls, a significant departure from linearity with upward curvature is denoted by a bar slanting to the right (the symbol "/"). If there was a significant departure from linearity with downward curvature, then the TD<sub>50</sub> is calculated without the data from the highest dose group, and a bar slanting to the left (the symbol "\") appears. We have adopted this convention to obtain the best estimate of TD<sub>50</sub> by using only the linear portion of the dose-response curve in the calculation.

When there are more than three dose groups (including controls) in the TD<sub>50</sub> calculation and there is a significant departure from linearity, the symbol "Z" is listed in column (14). When there is a blank space for the shape of the dose-response, there are two possible reasons. First, there may be only one dose group and a control group in the experiment, in which case there is not enough information to determine a curve shape. Most tests in the general literature have only a control and one dose group. Second, there may be no dose-related effect, in which case the code "no dre" appears in column (13) and "P = 1." appears in column (15).

(15) The two-tailed *p*-value appears in column (15), under the header "2Tailpvl." This value indicates the statistical significance associated with testing whether the slope of the dose-response curve is different from zero. All values are given to one significant figure. When there is no dose-related effect or the slope is negative, then "P = 1." appears in column (15). Due to rounding, the lowest *p*-value reported is *p* < 0.0005; a calculated *p*-value which is > 0.0005 and < 0.001 is reported as *p* < 0.001. Note that the significance level listed in this column determines which symbol will be plotted for the most potent site in each experiment.

(16) The opinion of the original author, as to the tumorigenicity of the test agent at the site for which the TD<sub>50</sub> was calculated, is given in the last column on the left side of the plot (16) under the heading "AuOp" for author's opinion. Our rule for reporting opinions from all sources of data has been to record all clearly stated evaluations of tumorigenicity at the site(s) included in a TD<sub>50</sub> calculation. Some special considerations about our codes for the opinions of authors from various sources are as follows.

**NCI/NTP Bioassays.** Our conventions for coding the author's opinions from the NCI/NTP Technical Reports are based upon the text of the Report, including the evaluation of the Clearinghouse on Environmental Carcinogens (Data Evaluation/Risk Assessment Subgroup), and the Tables of Analyses of Primary Tumors. An author's opinion is listed for all target sites except: Berkeley Mixes (MXB) and the statistical sites, i.e., those included in the Tables of Analyses but not considered evidence for carcinogenicity in the text of the Technical Report. For these cases, the opinion column is blank, as in lines 1, 1d, 1e, and 1f of the 1,2-dibromoethane example (Fig. 2).

A "c" in the author's opinion column indicates that the Clearinghouse evaluation or the text of the Report stated that at the site(s) on which TD<sub>50</sub> is based, the compound was carcinogenic under the conditions of the bioassay. See for example, the opinion column in the example for lines 1a, 1b, and 1c. An "a" indicates an opinion that the incidence of tumors at that site(s) was associated with administration of the compound under the conditions of the bioassay, or that the evidence for carcinogenicity was suggestive.

The symbol "-" will appear in the opinion column for the most potent site in an NCI/NTP bioassay to denote the evaluation that the compound was not carcinogenic in that sex of that species under the conditions of the bioassay. In most cases, the "-" appears for the TD<sub>50</sub> calculated for TBA, which is our convention whenever there is no evidence for carcinogenicity. For experiments evaluated as inadequate in the Technical Report, the opinion column is always blank. For a list of experiments evaluated as inadequate, see Appendix 12.

There are some cases when the "-" appears for a statistical site, i.e., one not evaluated as evidence for carcinogenicity in the Report, but which was statistically significant according to the Tables of Analyses of Primary Tumors and also had a TD<sub>50</sub> significance level of *p* < 0.05. When this TD<sub>50</sub> is the only evidence for a treatment-related effect, and thus the most potent site, we have indicated this by placing a "-" in the opinion column and flagging the TD<sub>50</sub> with a # sign in the plot just to the left of the TD<sub>50</sub> value. For example, refer to "calcium cyanamide," for female mice, line 697 in the large graphic output. Note that the *p*-value associated with the TD<sub>50</sub> determines the symbol plotted for the TD<sub>50</sub>; this is independent of the author's opinion.

For bioassays in which some target sites were evaluated as treatment-related, the statistical sites are also reported but the opinion column is left blank. In order to make it clear that the Report itself did not contain positive evaluations of any statistical sites, we put an "S" for statistical in the last column on the right side of the plot, column (28), under the header "Brkly Code."\*

\*For some chemicals, the NCI/NTP Technical Report indicated that experiments in one or more sex-species groups were inadequate carcinogenesis bioassays, primarily based on the insufficient survival of the animals on test. We have indicated this opinion by placing an asterisk ("\*") after the chemical name on the left side of the plot. See Appendix 12 for a list of the particular sex-species groups.

**Bioassays in the Published Literature.** In the general literature whenever the author evaluated the proportion of animals with tumors at a particular site as treatment-related, a “+” will appear in the opinion column (16) for the TD<sub>50</sub> calculated for that site. Such stated opinions as “positive,” “carcinogenic,” “active,” and “tumorigenic,” fit this category. The symbol “+” will only appear in the opinion column for a TD<sub>50</sub> in one of the following two cases: either, the author gave a positive opinion for the particular target sites included in the TD<sub>50</sub>, or in the occasional case where an author evaluated the compound as carcinogenic without specifying the target site, and we have indicated this with a “+” symbol in the opinion column for the category “all tumor bearing animals (tba).”

Similarly, the opinion column will contain a “-” only when either the author stated an opinion that the particular sites included in the TD<sub>50</sub> are negative, or the author concluded that there was no treatment-related effect in the experiment, in which case all sites reported for the experiment have a “-” in the opinion column.

Target sites which an author did not evaluate as positive are included in the database only when the statistical significance associated with an increased percentage of dosed animals with tumors is  $p < 0.05$  (standard chi-square test, one-sided  $p$ -value), or when the tissue is a mandatory site (liver and lung for mice and hamsters; liver for rats).

When no opinion about carcinogenicity is stated for sites which are nevertheless used for TD<sub>50</sub> calculations, the author's opinion column is left blank. This may occur either for mandatory sites, or for included sites which were not unequivocally evaluated by the author. In those rare cases where the author provided enough information to permit the combining of tissues and tumors into a mandatory site, the author's opinion column is also blank, since the mix was created especially for the database.

In summary, the symbol for the author's opinion column in the general literature reflects what the author actually stated in the paper. Sites evaluated as positive are given a “+”. Sites evaluated as negative are given a “-”. A “+” is used for tba when the compound was evaluated as positive, and no specific target site was evaluated as positive. For all other opinions the author's opinion column is blank.

Occasionally, when there is a “c” or an “a” in the opinion column for an NCI/NTP bioassay, or a “+” for a test from the general literature, the positive evaluation was made because the incidence among dosed animals was high in comparison to historical control incidences; this occurs, for example, when there is a rare tumor among the dosed animals. The actual numbers of animals bearing such tumors may be quite low, thus making the estimate of TD<sub>50</sub> unreliable. In such cases, we have indicated that the author's opinion was based on historical control comparisons by putting the words “+historical” in the TD<sub>50</sub> column. See, for example, “allyl chloride” for female mice, line 152 in the large plot.

(17,18) The plot continues on the right side (Fig.3), by first repeating the identification numbers given for each line on the left side of the output, e.g., 1, 1a, 1b, etc. In field (17) the chemical name is also repeated, followed by common synonyms, in some cases. In the example, “ethylene dibromide” and “EDB” are given as synonyms for 1,2-dibromoethane. The Chemical Abstracts Service registry number (CAS#) is reported in field (18); in the example, 106-93-4 (Fig.3).

(19) Under the header “RefNum”, is the unique reference number assigned to each paper in the database. For NCI/NTP bioassays, this is the number used in the computer tapes; here, c00522. In the case of 1,2-dibromoethane, NCI/NTP conducted two bioassays: in one, the compound was administered by gavage and in the other, by inhalation. In such cases, we have assigned a consecutive number to distinguish the second bioassay and have included the appropriate Technical Report number. NCI/NTP uses a single number for both bioassays.

(20, 21) The lower and upper confidence limits for each TD<sub>50</sub> are presented in (20) “LoConf” and (21) “UpConf,” respectively. When the abbreviation “n.s.s.” appears for either the lower or upper confidence limit, it denotes “not statistically significant.” Whenever the statistical significance of TD<sub>50</sub> is  $p > 0.01$ , then the upper 99% confidence limit will not be calculated; see, for example, line 1f for 1,2-dibromoethane (Fig.3). When the lower confidence limit is “n.s.s.” this usually indicates that there were no tumors or only one tumor of the specified type in the experiment, and the lower confidence limit was not estimable; most often this occurs for mandatory sites as in 1e in the 1,2-dibromoethane example. Occasionally the n.s.s. occurs for the lower confidence limit because 100% of dosed animals had the tumor(s) of interest and hence no lower confidence limit could be estimated with summary data.

(22–26) Beginning in (22) on the right side, and extending through (26), we report the proportion of animals with tumors and the average dose level in mg/kg body weight/day which we have calculated for each dose group in the experiment. The proportion of animals with tumors for TD<sub>50</sub> values which have been calculated with lifetable data are presented here in summary form, i.e., the number of animals with tumors by the end of the experiment.

Reading across (22)–(26), under “Cntrl” (22), we list the proportion of control animals with the tumor types in the TD<sub>50</sub> calculation; the average dose in the lowest dose group is given under “1Dose” (23); the proportion of animals in that group with the tumor(s) is listed under “1Inc,” for incidence, (24); the next highest average dose “2Dose” (25) and the proportion of those animals with the tumor(s) “2Inc” (26) is given next, etc., for as many dose groups as there are in the experiment.

Whenever the TD<sub>50</sub> was calculated without the data from the high dose group (i.e., there was a significant downward departure from linearity), we have indicated this fact with parentheses around the data which were omitted from the final calculation. Thus, whenever the

shape of the dose-response on the left side of the plot is "\\" column (14), the parentheses appear on the right side around the appropriate data. See, for example, 2-aminoanthraquinone for male rats, line 202 in the large plot. Whenever there were more than three groups (including controls), and the dose-response was non-linear, there is a "Z" in column (14) on the left side; if the departure from linearity in such cases was downward, then this fact is indicated by parentheses around the group that was excluded from the TD<sub>50</sub> calculation.

**NCI/NTP Bioassays.** For the data on the proportion of animals with tumors, the number of animals in each group is the number at the start of the experiment. In the example, there were 20 in the control group, and 50 in both the low and high dose groups. When pooled controls have been used as evidence for carcinogenicity in the Technical Report, we have calculated TD<sub>50</sub> values with those controls as well as the matched controls. (This convention has also been followed for the lifetable calculations of the experiments of aromatic amines.) Data using the pooled controls are indicated by the letter "p" following the control incidence in column (22); see, for example, "aldrin" for male mice in the large plot, line 135. The use of pooled controls is also reflected on the left side of the output by the word "pool" following the notes in column (10) and by assigning a different line number to the pooled data.

In the conduct of several of the NCI/NTP bioassays, the dose level administered to the high dose group was sufficiently toxic to necessitate starting a new dose group and a new control group. For some of the bioassays in which this was done, the statistical analysis in the Technical Report was performed separately for the control and dose groups which were started later. For these cases, we compared the proportion of animals with tumors in the earlier and later control groups, and since we found no significant difference, we combined the data from the control groups and analyzed the experiment as one dose response, using both the high and low dose groups. Appendix 10, "NCI/NTP Bioassays with Combined Controls," lists all such cases.

In some instances, the data for the proportion of animals with tumors is slightly different from what is reported in the Technical Report because the pathology diagnoses were updated after the Report was published; the revised data were on the computer tapes provided to us. These cases are listed in Appendix 11, "NCI/NTP Bioassays with Revised Data."

**Bioassays in the Published Literature.** The proportion of animals with tumors presented here reflects exactly the number of animals used in the TD<sub>50</sub> calculation. Many authors have reported only the starting number of animals. Whenever additional information was given, i.e., number of animals alive at the time of appearance of the first tumor, or number examined histologically, then this number is used in the denominator of the proportion of animals with tumor. This is a more accurate description of the number of animals at risk of tumor. These data were used in the TD<sub>50</sub> calculation and are reflected in columns (22), (24) and

(26). In these cases, the notecode "e" for "effective number" appears on the left side of the plot under "Notes" in column (10). Otherwise, the data reflect the number of animals started in each group. Since experimental designs vary in the literature, the incidence and dose-rate data may include a control and only one dose group or perhaps, a control and several dose groups.

In the general literature, pooled control data reported by the author are used in TD<sub>50</sub> calculations only when no matched data were reported. Our conventions for plotting pooled data are the same as those described for the NCI/NTP bioassays.

(27) Reading across the right side of the plot, under "Citation or Pathology" for the NCI/NTP bioassays, we present the three-letter codes for all of the sites and histopathology which are "Author's Mix" (MXA) or "Berkeley Mix" (MXB). This includes the MXB mandatory liver and lung pathologies, our combinations of sites which were individually evaluated as positive in the Report (MXB), the statistical sites which included more than one site in the Tables of Analyses (MXA), and any combination of sites evaluated as treatment-related in the Technical Report (MXA). The three-letter code for each tissue in the TD<sub>50</sub> calculation is followed by a ":" and then by the three-letter codes for each category of neoplasm included in the calculation. A ":" follows the last three-letter tumor code in each mix. The definitions for these codes are given in Appendices 5 and 6.

For the published literature, a citation to the paper is provided, giving the first author, code for the journal or book title, volume number, pages, and year. The full titles of the four-letter codes for the names of references are listed in Appendix 9, "Reference Codes and Definitions." The abbreviation "pers.comm." indicates that additional data for the TD<sub>50</sub> calculation were acquired through personal communication with the author(s). On the plot a new citation for a published paper is listed whenever there is a change in paper. When the following experiment is an NCI/NTP bioassay, then codes for pathology appear in field (27) instead of a citation. In Appendices 14 and 15 we have provided a complete bibliography of all papers in the database. Appendix 14 includes the articles, books, and reports in the general literature; Appendix 15 lists the NCI/NTP Technical Reports.

(28) The last column of the plot, is used only for NCI/NTP bioassays. Under the header "Brkly Code," we indicate that a TD<sub>50</sub> has been included in the database because of a decision by the Carcinogenic Potency Project (Berkeley) rather than because the sites were evaluated as treatment-related in the NCI/NTP Technical Report.

The letters "C," "A" and "T" are used in the Berkeley Code column for Berkeley Mixes (MXB). The letter "C" denotes a TD<sub>50</sub> calculated for all sites evaluated in the Technical Report as evidence for carcinogenicity. (Fig. 3). The letter "A" denotes a combination of tumors evaluated as associated with administration of the compound. The letter "T," for together, denotes a

combination of all sites evaluated as "C" or "A" in a bioassay where the weaker "associated" opinion and the stronger "carcinogenic" opinion were both reported. The letter "S" indicates that the TD<sub>50</sub> has been included in the plot because the sites were statistically significant in the Tables of Analyses of Primary Tumors and the TD<sub>50</sub> was significant at the  $p < 0.05$  level; however, no positive opinion was provided in the Report. An "S" may appear for either a mix of sites or a single site. For all mandatory sites, the column for "Brkly Code" is blank.

The information in the plot is ordered systematically to facilitate use of the data. All bioassays of a particular chemical are organized under the chemical name, and these names are ordered alphabetically. Within each compound, the bioassays are ordered alphabetically by species code, so that dogs would appear first, then hamsters, mice, prosimians, monkeys, and finally rats. Within a species, the bioassays are ordered by the code for the strain or stock. (For monkeys and prosimians, the tests are ordered by the code for the species.) If there is an NCI/NTP bioassay of the chemical, then all experiments using that strain are reported first, followed by the strain used in any other experiments providing lifetable data, and finally by any remaining strains ordered alphabetically. Within the strain, the bioassays of females are reported first. Thus, when there is an NCI/NTP bioassay, "b6c" mice will appear first, and all experiments using "b6c" female mice would be reported before any experiments using "b6c" males.

The reader may find it convenient, when utilizing the plot, to refer back to this guide. Abbreviations and symbols are defined in detail in the Appendices. When using the database, readers may find that we have not identified an experiment which does meet the standard inclusion criteria. Therefore, we welcome information about additional tests, as well as corrections of any errors in the database.

We wish to thank Jerrold Ward and Kenneth Chu for their valuable and consistent expertise in pathology and toxicology during the course of our work. For their significant contributions we would like to acknowledge Cathy St. Hilaire and Robert Harris in the early stages of this project, and Mary Argus, Susan Sieber, and Joan Staats more recently. Numerous experimentalists have assisted us in the interpretation and details of their published papers, and we are grateful for their time and work.

This work was completed with the assistance also of D. Ang, J. Bertucelli, M. Blumenthal, M. DaCosta, A. Friedman, K. Gould, T. Haggan, E. Higgins, H. Hurd, P. Kato, T. Liou, P. M. MacLeod, M. Needels, M. Nichols, M. Rosenfeld, W. E. Rouse and M. Smith.

This work was supported by NIEHS/DOE Interagency Agreement 222-Y01-AS-10066 and EPA-NCI/DOE Interagency Agreement Y01-CP-15791 through the Lawrence Berkeley Laboratory, and by DOE Contract DE-AT03-80EV70156 to B.N.A.

## APPENDIX 2: CHEMICAL NAMES LISTED BY CAS NUMBER

CAS NUMBER <sup>a</sup>	CHEMICAL NAME
mixture	3-AMINO-9-ETHYLCARBAZOLE MIXTURE (3-amino-9-ethylcarbazole and 3-amino-9-ethylcarbazole.HCl. CAS NUMBER 132-32-1 and 6109-97-3)
mixture	HClD MIXTURE (1,2,3,7,8,9-hexachlorodibenzo-p-dioxin and 1,2,3,6,7,8-isomer, CAS NUMBER 19408-74-3 and 57653-85-7)
mixture	STYRENE AND beta-NITROSTYRENE MIXTURE (CAS NUMBER 100-42-5 and 102-96-5)
mixture	VANGUARD GF (ferric nitrosodimethylthiocarbamate and tetramethylthiuram disulfide, CAS NUMBER --- and 137-26-8)
mixture	METHYLAZOXYMETHANOL ACETATE AND CYCASIN MIXTURE (CAS NUMBER 592-61-1 and 14901-08-7)
50-06-6	PHENOBARBITAL (phenobarbitone)
50-07-7	MITOMYCIN-C
50-14-6	VITAMIN D2
50-18-0	CYCLOPHOSPHAMIDE (Endoxan)
50-23-7	HYDROCORTISONE (cortisol)
50-28-2	ESTRADIOL (estradiol-17beta)
50-29-3	DDT
50-32-8	BENZO(a)PYRENE
50-44-2	6-MERCAPTOPURINE
50-55-5	RESERPINE
50-78-0	ACTINOMYCIN D
50-78-2	ASPIRIN
51-02-5	PRONETHALOL.HCl (alderlin.HCl)
51-03-6	PIPERONYL BUTOXIDE
51-21-8	5-FLUOROURACIL
51-28-5	2,4-DINITROPHENOL
51-52-6	PROPYLTIOURACIL
51-65-8	ATROPINE
51-75-2	NITROGEN MUSTARD (2,2'-dichloro-N-methyldiethylamine)
51-79-6	URETHANE
52-24-4	THIO-TEPA
53-19-0	o,p'-DDD
53-70-3	DIBENZ(a,h)ANTHRACENE
53-96-2	N-HYDROXY-2-ACETYLAMINOFLUORENE (hydroxy-N-2-fluorenylacetamide)
53-96-3	2-ACETYLAMINOFLUORENE (N-2-fluorenylacetamide)
54-11-6	NICOTINE
54-80-8	PRONETHALOL (alderlin)
54-85-3	ISONIAZID (INH)

CAS NUMBER <sup>a</sup>	CHEMICAL NAME
55-18-5	N-NITROSODIETHYLAMINE (DEN)
55-22-1	ISONICOTINIC ACID
55-38-9	FENTHION
55-98-1	MYLERAN (busulfan)
56-04-2	METHYLTHIOURACIL
56-23-5	CARBON TETRACHLORIDE
56-38-2	PARATHION
56-49-5	3-METHYLCHOLANTHRENE
56-63-1	DIETHYLSTILBESTROL (DES)
56-72-4	COUMAPHOS
56-75-7	CHLORAMPHENICOL (Chloromycetin)
57-13-6	UREA
57-14-7	1,1-DIMETHYLHYDRAZINE
57-30-7	PHENOBARBITAL, SODIUM (phenobarbitone, sodium)
57-39-6	METEPA
57-41-0	5,5-DIPHENYLHYDANTOIN
57-50-1	SUCROSE
57-55-6	PROPYLENE GLYCOL
57-57-8	beta-PROPIOLACTONE
57-74-9	CHLORDANE
57-97-6	7,12-DIMETHYLBENZ(a)ANTHRACENE
58-08-2	CAFFEINE
58-14-0	PYRIMETHAMINE (Daraprim)
58-89-9	gamma-1,2,3,4,5,6-HEXAChlorOCYCLOHEXANE (lindane)
59-05-2	METHOTREXATE
59-35-8	4,6-DIMETHYL-2-(5-NITRO-2-FURYL)PYRIMIDINE
59-87-0	5-NITRO-2-FURALDEHYDE SEMICARBAZONE
59-88-1	PHENYLHYDRAZINE.HCl
60-11-7	N,N-DIMETHYL-4-AMINOAZOBENZENE (DAB)
60-34-4	METHYLHYDRAZINE
60-35-5	ACETAMIDE
60-51-6	DIMETHOATE
60-56-0	METHIMAZOLE

ule	undifferentiated leukemia
vsc	all vascular tumors

\*NOS = not otherwise specified.

## APPENDIX 7: NOTECODES AND DEFINITIONS

Code	Definition
a	The exposure time reported on the plot is an average of the different exposure times of the individual dose groups in the experiment. In addition, for NCI/NTP bioassays an "a" may indicate that all animals in one group were dead long before those in another group, and therefore the experiment time on the plot is an average of experiment times for the different dose groups. (In the TD <sub>50</sub> calculation for the NCI/NTP bioassays, full lifetable data have been used.)
b	Diet was specially prepared to be deficient in one or more vitamins.
d	A cyclic dosing schedule was followed for part of the exposure time, with at least one week between cycles, e.g., 3 weeks dosed, one week not dosed.
e	For the general literature we have used an effective number of animals in a group whenever possible. This effective number is either: (1) the number of animals examined, or (2) the number of animals alive at the time of appearance of the first tumor. For some NCI/NTP bioassays the Technical Report includes both time-adjusted and unadjusted statistical analyses. Effective number indicates that some sites in these experiments have been included in the plot on the basis of the time-adjusted analysis.
f	Diet was specially prepared to have a lower than average protein level.
g	Some or all of the animals were used as breeders during the course of the experiment.
k	For interim and serial sacrifice experiments, we have reported each sacrifice time as a separate experiment. The k notecode identifies these sacrificed groups. Unscheduled deaths have been included with the terminal sacrifice data, wherever possible and do not receive a notecode.
m	The calculated dose level for a group is an average of either (1) different doses administered to individual animals, or (2) the range of doses administered.
r	Authors either examined or chose to report data for only a few selected tissues. Therefore, this is a restricted site analysis.
s	Authors noted that survival was decreased due to toxicity or disease.
u	Tests in monkeys are still in progress. The vinylidene chloride experiment in mice has been completed, but the final report has not yet been published.
v	Variable or irregular dosing schedules have been used, e.g., dose level changed during the experiment.
w	Monkey control animals are from a colony which includes both vehicle and untreated controls. Some animals have been used as breeders. Seventy percent of the animals are born in the colony; thirty percent are brought in from the wild as adults. The age of controls ranges from neonate to greater than 16 years. Only controls which have died are included in the TD <sub>50</sub> calculations.
x	Exposure began before the animals were weaned.

Code	Definition
y	In experiments from two papers, animals were dosed for only 25 weeks; one week short of the standard criterion. Due to rounding, 6 months is reported as the exposure time on the plot.
z	In a report of these vinyl chloride experiments (20), the author notes "All the animals exposed to the highest doses (30,000 and 10,000 ppm for 52 weeks), with or without tumors, were examined radiologically during treatment and/or at death; moreover, radiologic examinations have also been made on several animals bearing tumors even though these animals had been exposed to the lower doses." The experiment at the highest dose (30,000 ppm) is not included in the database. The reported data include the 10,000 ppm or lower doses.

#### APPENDIX 8: DOSE-RESPONSE CURVE SYMBOLS AND DEFINITIONS

Symbol	Dose-Response Curve
*	consistent with linearity
/	significant departure from linearity, upward curvature
\	significant departure from linearity, downward curvature
Z	significant departure from linearity, more than three dose groups including controls
blank	either no dose-related effect, or only two dose groups including controls, so not enough information to determine a curve shape

#### APPENDIX 10: NCI/NTP BIOASSAYS WITH COMBINED CONTROLS

Chemical Name	Experiments with Combined Controls
ACRONYCINE	rats, female mice
3-AMINO-4-ETHOXYACETANILIDE	rats, mice
2-AMINOANTHRAQUINONE	mice
2,4-DIAMINOANISOLE SULFATE	rats, mice
2,5-DIAMINOTOLUENE SULFATE	rats, mice
2,4-DINITROTOLUENE	rats, mice
FENAMINOSULF, FORMULATED	female mice
HYDRAZOBENZENE	rats, mice
5-NITRO-o-ANISIDINE	rats, mice
5-NITROACENAPHTHENE	rats
4-NITROANTHRANILIC ACID	rats, mice
6-NITROBENZIMIDAZOLE	rats, mice
1-NITRONAPHTHALENE	rats, mice
PHENESTERIN	mice
STYRENE	rats
THIO-TEPA	rats

#### APPENDIX 11: NCI/NTP BIOASSAYS WITH REVISED DATA

Chemical Name	Experiments with Revised Data
2-AMINOANTHRAQUINONE	rats, mice
AZINPHOSMETHYL	rats, mice
CAPTAN	rats
CHLORAMBEN	rats

Chemical Name	Experiments with Revised Data
1,2-DICHLOROETHANE	rats
DICOFOL	mice
DIELDRIN, PHOTO-	rats
1,4-DIOXANE	mice
DIOXATHION	rats, mice
ENDRIN	rats, mice
HYDRAZOBENZENE	rats, mice
2-METHYL-1-NITROANTHRAQUINONE	mice
5-NITRO-o-TOLUIDINE	rats, mice
PHOSPHAMIDON	rats
PICLORAM	rats

#### APPENDIX 12: NCI/NTP BIOASSAYS EVALUATED AS INADEQUATE IN TECHNICAL REPORTS

Chemical Name	Experiments Evaluated as Inadequate
ACRONYCINE	mice
ALLYL CHLORIDE	rats
5-AZACYTIDINE	rats, male mice
CHLOROPICRIN	rats
CLONITRALID	male mice
m-CRESIDINE	male mice
DIBUTYLTIN DIACETATE	female rats
EMETINE·2HCl	rats, mice
ENDOSULFAN	male rats, male mice
NITROFEN	male rats (C00421 only)
PHOSPHAMIDON	rats
PROFLAVINE·HCl HEMIHYDRATE	rats, mice
PYRAZINAMIDE	female mice
PYRIMETHAMINE	male mice
TETRACHLOROETHYLENE	rats
β-THIOGUANINE DEOXYRIBOSIDE	mice
1,1,1-TRICHLOROETHANE	rats, mice
TRICHLOROFLUOROMETHANE	rats

#### APPENDIX 13: NONHUMAN PRIMATES

A special literature search was conducted for chemical carcinogenesis experiments in nonhuman primates. While many research reports were identified, few fit the standard inclusion criteria used for the rest of the database. Most of the tests did not meet the inclusion rules for one of the following reasons: (1) fewer than five dosed animals; (2) no control group; or (3) short experiment time.

We subsequently relaxed the standard criteria in order to include tests from which a reasonable estimate of  $TD_{50}$  could be made. The major change has been to reduce the required experiment length from half the standard lifespan to 3 years for monkeys and 2 years for bush babies, if the author evaluated the compound as carcinogenic in that short time. The  $TD_{50}$  values from these shorter tests have been calculated with an extrapolation factor greater than that for other tests in the database, and are therefore less reliable. These cases are flagged in the plot with parentheses around the  $TD_{50}$ .

Most of the experiments on nonhuman primates in the database are from the Laboratory of Chemical Pharmacology, National Cancer Institute (NCI). Several of these experiments are still in progress and have been included in the database only if the researchers have already reported that the test compound is carcinogenic. We have excluded experiments still in progress and without evidence of carcinogenicity because tumor induction may still occur. (For example, the test of saccharin is excluded.) The  $TD_{50}$  calculations for the experiments still in progress are based only on dosed and control animals which have already died.

Some special considerations about these tests from the Laboratory of Chemical Pharmacology, (NCI) are as follows: (1) Data for males and females have been combined because the results for both sexes of control animals were reported together. (2) Histopathology was reported only for malignant neoplasms. (3) The first dose was usually administered at birth; however, in some experiments, the age at first dose ranged from neonate to adult. (4) Dosing may have been as infrequent as one time per month. (5) Monkey control animals are from a colony which includes both vehicle and untreated controls. Some animals have been used as breeders. Seventy percent of the animals are born in the colony, 30% are brought in from the wild as adults. The age of controls ranges from neonate to greater than 16 years. Only controls which have died are included in the TD<sub>50</sub> calculations. (6) For one compound, procarbazine-HCl, we accepted subcutaneous injection as a route of administration when given in combination with either diet or intraperitoneal injection.

## APPENDIX 15

### BIBLIOGRAPHY

National Cancer Institute/National  
Toxicology Program Technical Reports

All Technical Reports are entitled "Bioassay of [Chemical Name] for Possible Carcinogenicity"

<u>CHEMICAL NAME</u>	<u>TECHNICAL REPORT NUMBER</u>	<u>PUBLICATION DATE</u>
ACETOHEXAMIDE	50	1978
ACRONYCINE	49	1978
ALDICARB	136	1979
ALDRIN	21	1978
ALLYL CHLORIDE	73	1978
3-AMINO-4-ETHOXYACETANILIDE	112	1978
3-AMINO-9-ETHYLCARBAZOLE HYDROCHLORIDE	93	1978
1-AMINO-2-METHYLANTHRAQUINONE	111	1978
4-AMINO-2-NITROPHENOL	94	1978
2-AMINO-5-NITROTHIAZOLE	53	1978
2-AMINOANTHRAQUINONE	144	1978
ANILAZINE	104	1978
ANILINE HYDROCHLORIDE	130	1978
<i>o</i> -ANISIDINE HYDROCHLORIDE	89	1978
<i>p</i> -ANISIDINE HYDROCHLORIDE	116	1978
ANTHRANILIC ACID	36	1978
AROCLOR 1254	38	1978
5-AZACYTIDINE	42	1978
AZINPHOSMETHYL	69	1978
AZOBENZENE	154	1979
1H-BENZOTRIAZOLE	88	1978
$\beta$ -TGdR	57	1978
BIS(2-CHLORO-1-METHYLETHYL) ETHER	191	1979
BUTYLATED HYDROXYTOLUENE (BHT)	150	1979
C.I. VAT YELLOW 4	134	1979
CALCIUM CYANAMIDE	163	1979
CAPTAN	15	1977
CARBROMAL	173	1979
